CEUs for pesticide license renewal

Earn CORE CEUs online through articles written by UF-IFAS Citrus Extension Agents in the Citrus Industry magazine http://citrusindustry.net/ceu/

The following series of articles and quizzes are available with their expiration dates noted:

- 2023 #4: How to Properly Transport and Store Pesticides (10/31/24)
- 2023 #3: A Guide to Safe, Effective Pesticide Use (7/31/24)
- 2023 #2 What To Do When You’ve Been Exposed to a Pesticide (4/30/24)
- 2023 #1: Key Terms to Know When Using Pesticides (1/31/24)

Each article grants one General Standards (Core) CEU when submitted and approved toward the renewal of a Florida Department of Agriculture and Consumer Services restricted-use pesticide license.
The objective of the Florida Citrus Production Guide is to assist citrus growers in the identification of pest management options and the selection of appropriate control measures. This publication should serve as a reference once it has been determined that control measures might be warranted. It is not intended to replace pesticidal product labels which contain important usage information and should be immediately accessible for reference. Violations of directions for use printed on the label are against State and Federal laws. Care should be taken to select only those treatments best suited for control of the specific pest(s) identified as requiring suppression. Products listed in all tables have been shown to be efficacious, non-phytotoxic to citrus, and relatively safe on non-target arthropods and microorganisms when used as directed. However, it is important to realize that results may not be consistent under different environmental, application, and tank mix conditions.

Synopsis: El Niño is anticipated to continue through the Northern Hemisphere spring (with a 62% chance during April-June 2024). Above-average sea surface temperatures (SST) across the equatorial Pacific Ocean [Fig. 1] were indicative of a strong El Niño, with anomalies increasing in the central and east-central Pacific in the past month. The latest weekly Niño index values were +1.4°C in Niño-4, +1.8°C in Niño-3.4, +2.1°C in Niño-3, and +2.2°C in Niño-1+2 [Fig. 2]. Area-averaged subsurface temperatures anomalies increased slightly [Fig. 3] associated with the initiation of a downwelling oceanic Kelvin wave, which strengthened above-average subsurface temperatures in the central equatorial Pacific [Fig. 4]. Low-level wind anomalies were westerly in the east-central Pacific, while upper-level wind anomalies were easterly in the western and central Pacific. Convection/rainfall was enhanced around the International Date Line, extending into the eastern Pacific. Suppressed convection/rainfall strengthened around Indonesia [Fig. 5]. The equatorial Southern Oscillation Index (SOI) and the station-based SOI remained negative. Collectively, the coupled ocean-atmosphere system reflected a growing El Niño. The most recent IRI plume favors El Niño to continue through the Northern Hemisphere spring 2024 [Fig. 6]. Based on latest forecasts, there is a greater than 55% chance of at least a "strong" El Niño (≥ 1.5°C in Niño-3.4 for a seasonal average) persisting through January-March 2024. There is a 35% chance of this event becoming "historically strong" (≥ 2.0°C) for the November-January season. Stronger El Niño events increase the likelihood of El Niño-related climate anomalies, but do not necessarily equate to strong impacts (see CPC seasonal outlooks for probabilities of temperature and precipitation). In summary, El Niño is anticipated to continue through the Northern Hemisphere spring (with a 62% chance during April-June 2024; [Fig. 7]).

This discussion is a consolidated effort of the National Oceanic and Atmospheric Administration (NOAA), NOAA's National Weather Service, and their funded institutions. Oceanic and atmospheric conditions are updated weekly on the Climate Prediction Center web site (El Niño/La Niña Current Conditions and Expert Discussions). Additional perspectives and analysis are also available in an ENSO blog. A probabilistic strength forecast is available here. The next ENSO Diagnostics Discussion is scheduled for 14 December 2023.

1 Net pounds per box: oranges in California-80, Florida-90, Texas-85; grapefruit in California and Texas-80, Florida-85; lemons-80; and tangerines and mandarins in California-80, Florida-95.
2 Early non-Valencia (including Navel) and midseason non-Valencia varieties in Florida; Navel and miscellaneous varieties in California; Early and mid-season varieties in Texas.
3 Estimates carried forward from October.
4 Includes pummelos in California.
5 Includes tangarinos.
All Oranges 20.5 Million Boxes
The 2023-2024 Florida all orange forecast released today by the USDA Agricultural Statistics Board is 20.5 million boxes, unchanged from the October forecast. If realized, this will be 30 percent more than last season’s final production. The forecast consists of 7.50 million boxes of non-Valencia oranges (early, mid-season, and Navel varieties) and 13.0 million boxes of Valencia oranges. An 8-year regression was used for comparison purposes. All references to “average”, “minimum”, and “maximum” refer to the previous 10 seasons, excluding the 2017-2018 season, which was affected by Hurricane Irma, and the 2022-2023 season, which was affected by Hurricanes Ian and Nicole. Average fruit per tree includes both regular bloom and the first late bloom.

Non-Valencia Oranges 7.50 Million Boxes
The forecast of non-Valencia production is 7.50 million boxes, unchanged from the October forecast. Current fruit size is projected to be below the minimum at harvest. Current dropage is above average and projected to be above average at harvest. The Navel forecast, included in the non-Valencia forecast, is 300,000 boxes, comprising 4 percent of the non-Valencia total.

Valencia Oranges 13.0 Million Boxes
The forecast of Valencia production is 13.0 million boxes, unchanged from October. Current fruit size is below average and is projected to be below average at harvest. Current dropage is projected to be above average at harvest.

All Grapefruit 2.40 Million Boxes
The forecast of all grapefruit production is 2.40 million boxes, up 500,000 boxes from the October forecast. If realized, this will be 33 percent more than last season’s final production. The red grapefruit, now at 2.10 million boxes, is increased 450,000 boxes from the October forecast. Fruit size of red grapefruit at harvest is projected to be above average, and dropage is projected to be average. The white grapefruit forecast is raised 50,000 boxes and is now 300,000 boxes. Projected fruit size of white grapefruit at harvest is slightly above average while projected dropage is below average.

Tangerines and Tangelos 550,000 Boxes
The forecast of tangerines and tangelos is 550,000 boxes, up 50,000 boxes from the October forecast. This forecast number includes all certified tangerine and tangelo varieties.

Reliability
To assist users in evaluating the reliability of the December 1 Florida production forecasts, the "Root Mean Square Error," a statistical measure based on past performance, is computed. The deviation between the December 1 production forecast and the final estimate is expressed as a percentage of the final estimate. The average of squared percentage deviations for the latest 20-year period is computed. The square root of the average becomes statistically the "Root Mean Square Error." Probability statements can be made concerning expected differences in the current forecast relative to the final end-of-season estimate, assuming that factors affecting this year’s forecast are not different from those influencing recent years.

The "Root Mean Square Error" for the December 1 Florida all orange production forecast is 10.2 percent. However, if you exclude the four abnormal production seasons (four hurricane seasons), the "Root Mean Square Error" is 8.4 percent. This means chances are 2 out of 3 that the current all orange production forecast will not be above or below the final estimate by more than 10.2 percent, or 8.4 percent excluding abnormal seasons. Chances are 9 out of 10 (90 percent confidence level) that the difference will not exceed 17.7 percent, or 14.7 percent excluding abnormal seasons.

Changes between the December 1 Florida all orange forecast and the final estimates during the past 20 years have averaged 7.28 million boxes (6.75 million, excluding abnormal seasons), ranging from 0.95 million boxes to 18.2 million boxes including abnormal seasons, (1.30 to 16.3 million boxes excluding abnormal seasons). The December 1 forecast for all oranges has been below the final estimate 2 times, above 18 times, (below 2 times, above 14 times, excluding abnormal seasons). The difference does not imply that the December 1 forecast this year is likely to understate or overstate final production.

Forecast Components, by Type -- Florida: December 2023
[Survey data is considered final in December for Navel oranges, January for early-midseason (non-Valencia) oranges, February for grapefruit, and April for Valencia oranges]

¹ Excludes Navels.
Flower bud advisory #2 is now available at https://cerc.ifas.ufl.edu/research/citrus-production/flower-bud-induction/.

By Dr. Tripti Vashisth

Season Forecast: This is predicted to be an El Niño–Southern Oscillation (ENSO) winter, which means Florida will experience more rainfall pattern than normal. The daily temperatures are predicted to be average for this time of year, however, due to higher than usual rainfall (associated overcast) slightly cooler temperatures can be predicted.

Under these conditions, enough hours below 68°F are likely to accumulate to induce an economic level of flower buds, but excessive rainfall can interfere with bud induction as both low temperature and drought stress are needed for strong floral bud induction.

Current Condition: Currently, most of the citrus producing regions are in low to moderate flower induction levels. So far Umatilla has accumulated about 590 IH, areas surrounding Lake Alfred are about 470 IH, Immokalee at 430 IH, and Indian River at lowest accumulation, around 420 IH. Generally, once the trees are in low to moderate induction an intermittent warm period along with rainfall can be sufficient to induce bud break thus leading to prolonged bloom however, under current predicted conditions (in majority of citrus producing region) we do not expect many hours above 75°F for next two weeks, thus day temperature should not be conducive for significant bud break.

Next 15 days will be intermediate for cool temperature accumulation with about 150 to 200 IH in most of the citrus producing area. More IH in next couple of weeks will be good and push the trees toward moderate to high flower bud induction period. Once the trees are in moderate to high floral induction, a rainfall along with extended warm temperatures can be sufficient to advance bud break leading to multiple blooms. If you are in region of Florida where warm temperature along with rainfall is predicted, multiple waves of flowering can be expected as the warm spell can push the induced buds. In such cases to suppress prolonged/multiple waves of flowering consider spraying gibberellic acid in next couple of weeks. Keep track of induction hours in your area.

General Information: Cool weather stops growth and then promotes induction of flower buds as more cool weather accumulates. After moderate induction, a warm spell when coincides with rainfall can initiate differentiation, which after sufficient days of warm temperatures will lead to bloom. Trees will be very vulnerable to growth stimulation by a warm period (over 75°F) after they accumulate 300-400 hours of cool temps if soil moisture is adequate.

Keep track of induction hours in your area and watch for projected warm periods from the weather services. Normal healthy trees could have their induction boosted by applying some drought stress. Unfortunately, with vulnerable root systems associated with HLB you shouldn’t risk heavier preharvest fruit drop of the current crop by using water stress to prevent unwanted early vegetative growth and enhance induction of flowers. Based on weather predictions, if you are concerned about early flowering in your region, a gibberellic acid (GA) application can prevent some early flowering.
**Gibberellic Acid Application Consideration:** Gibberellic acid sprays can be used to suppress early spring flowering but the timing of application is critical for GA to be effective. GA (to suppress flowering) should be applied before warm temperatures (that is before differentiation begins). Previous research on HLB-affected trees has shown that when GA applied monthly in fall, early flowering was suppressed. Therefore, if you have a weak crop load and are forecasted to have warm spells, GA application can be considered to suppress off season flowering.

GA induced suppression of flowering benefits HLB-affected trees by preserving carbohydrate that can be later used by growing fruit and tree. Therefore, growers who are considering GA application to suppress flowering should carefully choose time to spray. GA application should be targeted at moderate-high flower bud induction period to get most effect. A late GA application might not be useful either. *As a general rule of thumb in most of the citrus producing regions of Florida moderate to high flower bud induction should be by 2-3rd week in December. Therefore, a GA spray in second or third week of December can be effective in reducing floral bud induction.* Once the induction level is above 600 or 650 hours the spray will not completely stop all of the flowering, but a more concentrated flowering should occur after the second warm period.

DO NOT spray GA after first of January to manage flowering.

GA can keep the fruit green, therefore can be a concern for fresh market fruit.

**Flowering related management considerations for HLB-affected trees:**

- DO NOT drought stress HLB-affected trees even though drought stress promotes flower induction and suppress vegetative growth, you should not risk current crop due to additional drought stress. Drought stress can exacerbate fruit drop. Daily, lower volume irrigations to minimize fall drought stress is suggested, especially when the weather is warm,
- Flowering enhancing fertilizer to increase the number of flowers are NOT suggested for severely HLB-affected trees as they are very less likely to benefit because of 2 reasons: (1) HLB-affected trees have more dead wood therefore, there are fewer buds available to become flower, interestingly a good branch of severe HLB trees has same flowering potential as mild HLB trees. So additional flowering promoting fertilizer is not needed. (2) High twig dieback and low fruitlet retention is the main concern with severe HLB trees in regards to fruit set. Only 2% of the total flowers turn into harvestable crop therefore, pushing tree to flower more is not advisable as that is likely to waste trees’ energy and resources in extra flowers.

**UF/IFAS CITRUS RESEARCH AND EDUCATION CENTER**

FLOWER BUD INDUCTION
Asian citrus psyllid (ACP) control has been the main objective of Florida citrus growers for more than 10 years. While some may question the value of controlling ACP in trees with high HLB incidence, replicated field studies have shown the economic benefit of maintaining young flush pathogen free. Good ACP control starts with effective dormant sprays that will control ACP when populations are low, reducing ACP infestation and thus HLB infection of the all-important spring flush. Pyrethroids (Danitol, Baythroid or Mustang) and organophosphates (dimethoate, chlorpyrifos, or Imidan) provide great winter season control of ACP. Best not to use pyrethroids or OPs again during the year except for border sprays which will reduce the need for whole block applications. Follow up with bloom sprays of labeled products to clean up stragglers. Subsequent whole block sprays should target ACP as well as other pests like rust mites and leafminers that may be problematic.

The table below offers alternative products for different months, depending on which pests are of major concern at the time. Neonicotinoids like imidacloprid, thiamethoxam or clothianidin have not been included as spray options due to their importance for controlling ACP in young trees. Superscripts after the pesticide name are now in sequential order to facilitate use and correspond to superscripts after pests controlled. Make choices based on: (1) effectiveness against ACP and other pests that may be problematic, (2) avoiding repetition of any insecticide mode of action in the interest of resistance management, and (3) rebuilding and maintaining an effective natural enemy complex in the grove. Confining the broad-spectrum insecticides (pyrethroids and organo-phosphates) to the winter season and border sprays during growing season will help conserve these products as well as populations of beneficial insects and mites.

2023 - 2024 WINTER WEATHER WATCH PROGRAM

NOVEMBER 15, 2023 TO MARCH 15, 2024
REGISTRATION FEE: $100.00

It's once again time to register for the upcoming 2023 - 2024 Winter Weather Watch Program. Upon receiving your $100.00 registration payment, you will be sent an unlisted telephone number with which you can retrieve the latest **Ag Forecasts**, 24/7. **Please do not give this number to others.** The Winter Weather Watch Program is funded by the registration fees to pay for telephone equipment rentals, long distance calls, repairs and our consulting meteorologist. I will be putting a text messaging list together for notifying subscribers of unscheduled weather forecast updates. If you would please indicate which number to use for this service in the following format on your subscription form, i.e. (863) 519-1052 (txt). One additional request would be to indicate the counties that you are interested in receiving weather forecasts. If you have one that is not listed please let me know and I might be able to take it under consideration.

2023 - 2024 Winter Weather Watch Program

The 2023-24 edition of the Winter Weather Watch program will begin on November 15, 2023. The program provides growers with winter weather forecast information specifically geared toward agricultural interests in West Central and Southwest Florida. The program provides subscribers with an unlisted phone number for (24 hour/7 days a week) access to daily weather forecasts. The zone forecasts are from the National Weather Service (NWS) and are listed on the automated phone menu, so you can select the products you are interested in. Forecasts include the zone forecasts, 6-10 and 8-14 day outlook forecasts. In addition to the forecasts we have special weather narratives provided as needed in the event of freezing temperatures and a weekly outlook provided by our own meteorologist David Faysash (Fred Crosby is actually stepping back starting this season). When freezing temperatures are predicted in our area additional updates will include the afternoon zone forecast and the modified sunset brunt minimum temperature equation. We will also provide the weekly citrus leaf freezing temperatures (also available on FAWN) and the 2023-24 Winter Weather Watch manual.

Subscriptions for the Winter Weather Watch program are only $100.00 for the entire 4 month period (Nov 15 to Mar 15). The cost is about the same as one tank (well maybe two now days) of gas for your pickup truck. You can subscribe to the Winter Weather Watch by completing and returning a “subscription form” or calling Joy Spencer at 863-519-1041 or email at j.spencer@ufl.edu

**Forecast Schedule**

The following schedule lists the products available from the Winter Weather Watch. Please note with David onboard this season the forecast schedule has been modified. The times and specific days of the week and the forecasted minimum temperature dictate when these forecasts products will be updated. Our Winter Weather Watch area tentatively includes the following areas by county: Pasco, Hillsborough, Polk, Highlands, Hardee, Manatee, Sarasota, DeSoto, Charlotte, Lee, Glades, Hendry and Inland Collier.
Introducing David Faysash
David has a bachelor's and master's degree in Meteorology from the Florida State University. As a graduate student he specialized in satellite remote sensing of land surface temperatures and atmosphere-biosphere interactions. David teaches meteorology courses at Valencia College in Orlando and Hillsborough Community College in Tampa. He was the outreach director for the West Central Florida Chapter of the American Meteorological Society where he organized and taught teacher in-service trainings about the weather. David has lived in Wesley Chapel (Pasco County) since 2001 and has been avidly watching West Central Florida's weather since then.

Fred Crosby indicated he would be willing to work with David this first season with the idea of eventually passing the torch on to David. I have spoken with David and think that he will also bring additional insight to the NWS forecasts as related to our agricultural enterprises.

Suggested Use Pattern of Injectable Antimicrobials for Huanglongbing (HLB) Management (February 2023)

This document is a suggested use pattern of injectable antimicrobials in Florida citrus. This is not an official University of Florida recommendation. Information is based on FIFRA Section 24(c) Special Local Need Label for ReMedium Ti ™(10/28/2022) and Rectify™ (01/30/2023).

**Antibacterial Product Application Schedule**

Application schedule should be adjusted based on expected harvest time and flowering. The red boxes indicate possible timing of injection. Note that only one application per year is recommended, although non-bearing trees are allowed to be injected up to twice annually with a 4-month interval.

</tbody>
</table>

The latest possible injection application should be determined based on the 180-day PHI from the expected harvest date. Color scale from most desirable (dark) to least desirable (light).

**Application**
- DO NOT apply during bloom.
- Recommended use after harvest and during spring.
- Recommended to apply when leaves are fully expanded for efficient uptake and distribution within tree.
- Phytotoxicity can occur in the hottest months of the year.
- ONLY inject once product is fully dissolved.
- ONLY use freshly prepared solution and protect solution from sunlight.

**Injection Sites**
- Do not re-use injection sites.
- The rootstock is the recommended location for injection, but it may not always be possible.
- Subsequent injections should be above or below the initial site by 2 inches and to the right or left by 2 to 3 inches.
- Do NOT use any post-wounding treatments as these may interfere with wound healing.

**The Label is the Law!**
Refer to the label for additional information. This guide does not supersede the label.

**Antibacterial Programs Do Not Replace Asian Citrus Psyllid Management Programs.**

**Considerations**
- Injection into the trunk can cause significant damage to the tree.
- In all trees, it is best to minimize hole diameter.
- Trees with a trunk diameter of less than 2.5 inches are best not injected.
- Minimizing the hole size will minimize tree damage.

**Application Method**

- Injection

---

**Crop Type**

- Citrus (group 10-10): Grapefruit, lemon, lime, orange, tangelo, tangerine, citron, kumquat, pummelo, and hybrids of these.

---

**DANGER**

Muriatic acid is highly corrosive and can cause severe skin burns and eye damage. Do not inhale fumes.

**CAUTION**

Injection of oxytetracycline dissolved in acidified solution may cause trunk damage with long-term effects not yet established.

---

1. Mixers and injection device fillers
2. Applicators
3. At least a particulate respirator with any N, R, or P filter, NIOSH approval prefix TC-84-A

Muriatic Acid Safety

Muriatic acid, also known as Hydrochloric Acid or Hydrogen Chloride (HCl), is a highly caustic liquid. To protect workers from burns and other injuries, it is important to use appropriate safety precautions.

About the Gulf Citrus Growers Association

The citrus growers of southwest Florida are committed to supporting education as a long-term investment in the future of our industry. The first Gulf Citrus scholarship was awarded in 1992 through the Gulf Citrus Growers Association, a trade organization representing growers in Charlotte, Collier, Glades, Hendry and Lee Counties.

The Gulf Citrus Growers Association Scholarship Foundation was established in 2000 as a non-profit entity to oversee the distribution of these awards. Scholarship applications are accepted throughout the year and are reviewed semi-annually by a Scholarship Selection Committee comprised of academic and industry members. The number and amount of awards vary depending upon the number of applications received and available funds.

Applicants who are not selected may submit a new application for consideration in the next selection cycle. Previous award winners may also reapply.

Scholarship Criteria

Preferred requirements for scholarships are as follows:

AA, BS, MS and PhD Degrees:

- Completion of all placement testing and a declared major in agriculture or related major.
- Completion of 12 credit hours towards agriculture or related degree.
- Minimum overall grade point average of 2.5 for AA and BS degrees; 3.0 for MS and PhD degrees.
- A demonstrated commitment to complete the degree at a state college, community college or university.

Applicants must complete the attached application and have their official transcripts sent directly by their universities to:

Gulf Citrus Growers Association Scholarship Foundation, Inc.
